

Homework Assignment #1

Arun Krishnaraj, eid:ak37738

2020-09-10

Problems 1-5

```
792/11
## [1] 72
sqrt(pi)
## [1] 1.772454
exp(2)
## [1] 7.389056
256^(1/4)
## [1] 4
log(2)
## [1] 0.6931472
```

Problem 6

```
a <- 3
b <- 7
a*b
## [1] 21
```

Problem 7

```
v <- -2:4
w <- seq(from=1,length.out = 7)
v*w
## [1] -2 -2 0 4 10 18 28
```

`v*w` returns a vector composed of products for each element of `v` multiplied by the corresponding numbered element in `w`.

Problem 8

```
successes <- rbinom(100,1,.2)
successes
## [1] 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1 1 0 0 0 0 0 0 0 0 0 1 0 0 0 1
## [38] 0 0 0 0 0 1 0 0 0 0 1 0 1 0 0 0 0 1 1 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 1 0 1
## [75] 0 0 0 0 0 0 0 1 0 0 0 1 0 0 0 1 0 0 0 1 0 0 0 0 0 0 0
sum(successes)/100
## [1] 0.18
```

The simulated batch of 100 trials has a proportion of success of .22.

Problem 9

```
library(ggplot2)
successes <- rbinom(1000,100,.2)
hist(successes)
```

Problem 10

For fair sided dice, the probability of any of the numbers 1 to 6 being rolled is $\frac{1}{6}$. We can consider the two dice to be independent, so the the probability of rolling a 6 on both is $\frac{1}{6}^2$; since the probability of rolling any number on a fair die is the same, the probability of rolling a 3 on both dice is also $\frac{1}{6}^2$. The second roll of dice is independent of the first, making the probability of rolling pairs of 6's twice in a row $\frac{1}{6}^4$; this is true for rolling pairs of 3's twice in a row as well, so both observed roll patterns are just as probable.

Problem 11

- 0, since the lowest outcome on each die is a roll of 1.
- A sum of 5 can be composed of the following ordered roll pairs (1, 4), (2, 3), (3, 2), (4, 1). Each of these pairs occur with probability $\frac{1}{36}$, making the total probability of observing a sum of 5 $\frac{4}{36} = \frac{1}{9}$.
- A sum of 12 can only occur if both dice result in 6; this probability is thus $\frac{1}{6}^2 = \frac{1}{36}$.

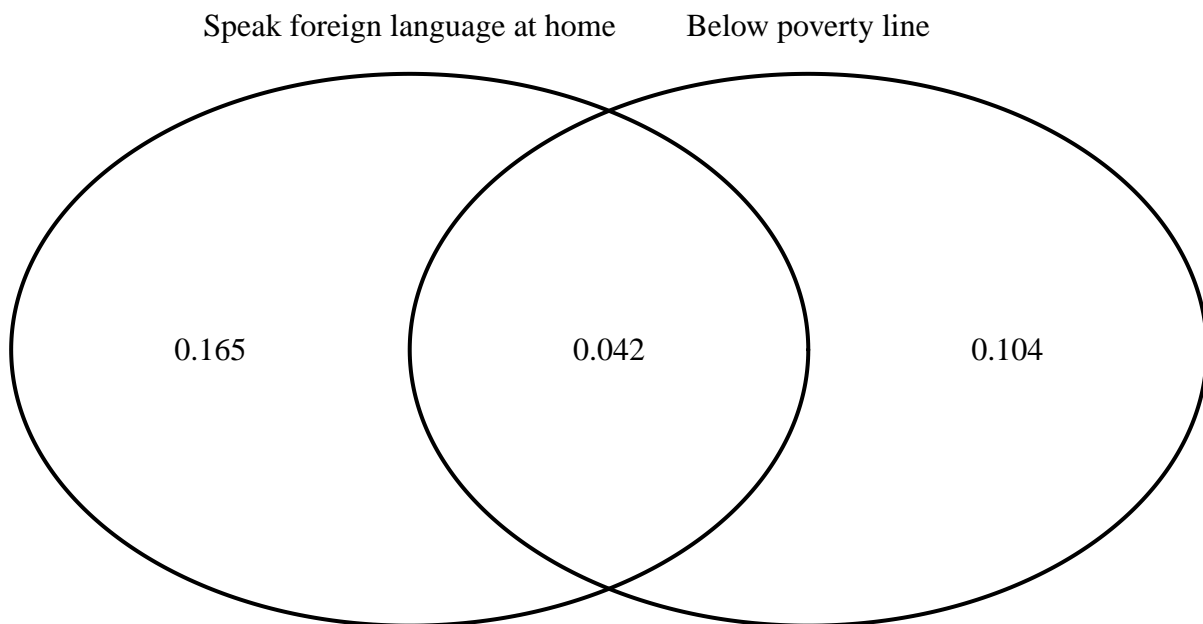

Problem 12

- No, since there are individuals who are in both categories
-

```

library(VennDiagram)
## Loading required package: grid
## Loading required package: futile.logger
grid.newpage()
venn.plot <- draw.pairwise.venn(area1      = .146,
                                area2      = .207,
                                cross.area = .042,
                                category    = c("Below poverty line", "Speak foreign language at home"),
                                cat.pos     = 0,
                                cat.dist    = .035,
                                scaled      = FALSE)

```

- c. 10.4% of Americans live below the poverty line and only speak English at home.
- d. 31.1% of Americans live below the poverty line or speak a foreign language at home.
- e. 68.9% of Americans live above the poverty line and only speak English at home.
- f. No; the probability that a person lives below the poverty line is 14.6% as provided. Given that a person speaks a foreign language at home, they have a $0.042/0.165 = 25.45\%$ probability of living below the poverty line. Since $P[\text{Living below poverty line}] \neq P[\text{Living Below Poverty Line} \mid \text{Speaking Foreign language at home}]$, the two events are not independent.

Problem 13

We can apply Bayes' rule to solve.

$$P[\text{Condition} \mid +] = \frac{P[+ \mid \text{Condition}] * P[\text{Condition}]}{P[+ \mid \text{Condition}] * P[\text{Condition}] + P[+ \mid \text{No Condition}] * P[\text{No Condition}]}$$

Given the information on proportion of people who have the condition and test accuracy for people with and without the condition, we obtain

$$P[\text{Condition}|+] = \frac{(.99) * (.03)}{(.99) * (.03) + (1 - .98) * (1 - .03)} = \frac{(.0297)}{(.0297) + (.0194)} = 0.605$$

So given that a randomly selected person tests positive for the predisposition, they have a 60.48% probability of actually having the predisposition.

Problem 14

We can again apply Bayes' rule to solve.

$$P[\text{In Favor}|\text{Degree}] = \frac{P[\text{Degree}|\text{In Favor}] * P[\text{In Favor}]}{P[\text{Degree}|\text{In Favor}] * P[\text{In Favor}] + P[\text{Degree}|\text{Against}] * P[\text{Against}]}$$

Using the provided information,

$$P[\text{In Favor}|\text{Degree}] = \frac{(.37) * (.53)}{(.37) * (.53) + (.44) * (1 - .53)} = \frac{(.1961)}{(.1961) + (.2068)} = .487$$

So given that a random exit poll participant had a college degree, there is a 48.67% probability that they voted in favor of Scott Walker.
